AIM: Implementation of Association rule mining Using

1. Apriori Algorithm

2. FPTree

THEORY:
Association rule learning is a type of unsupervised learning technique that checks for the dependency of one data item on another data item and maps accordingly so that it can be more profitable. It tries to find some interesting relations or associations among the variables of the dataset. It is based on different rules to discover the interesting relations between variables in the database.

The association rule learning is one of the very important concepts of machine learning, and it is employed in Market Basket analysis, Web usage mining, continuous production, etc. Here market basket analysis is a technique used by the various big retailers to discover the associations between items.

Association rules are created by thoroughly analyzing data and looking for frequent if/then patterns. Then, depending on the following two parameters, the important relationships are observed:

1. Support: Support indicates how frequently the if/then relationship appears in the database.
2. Confidence: Confidence tells about the number of times these relationships have been found to be true.

CODE:
Apriori

```python
import pandas as pd import numpy as np import math

transaction_df = pd.read_csv('GroceryStoreDataSet.csv')
```

```python
transaction_df

transaction_df.index.rename('TID', inplace=True)
transaction_df.rename(columns={'MILK,BREAD,BISCUIT' :
'item_list'}, inplace=True)

trans_df = transaction_df.item_list.str.split(',')

trans_df def prune(data,supp):

    df = data[data.supp_count >= supp]
return df def count_itemset(transaction_df,
itemsets):

    count_item = {} for
    item_set in itemsets:
    set_A = set(item_set) for
    row in trans_df:
            set_B = set(row)

            if set_B.intersection(set_A) == set_A:
                if item_set in count_item.keys():
                    count_item[item_set] += 1

                else:
                    count_item[item_set] = 1

    data = pd.DataFrame() data['item_sets']
= count_item.keys() data['supp_count'] =
count_item.values() return data def
count_item(trans_items):

    count_ind_item = {} for
    row in trans_items:
        for i in range(len(row)):
            if row[i] in count_ind_item.keys():
                count_ind_item[row[i]] += 1
```

```python
            else:
                count_ind_item[row[i]] = 1

    data = pd.DataFrame() data['item_sets'] =

CONCLUSION: We learnt about association rule mining and the two different algorithms that can be used - Apriori and FP Tree. We then learn about the uses of this algorithm and implemented the algorithm in a python program.
